## Introduction

This report details the Community Technical Assistance Program (CTAP) Buildout Analysis results for the Town of Bow, New Hampshire. CTAP is a five-year initiative designed to assist communities that will be affected by the rebuilding of I-93. This buildout, one of 26, is designed to allow a community to assess their future needs and help them reduce any negative consequences from the increased development pressure caused by the widening of I-93.

### What is CTAP?

CTAP is a joint effort between the 26 communities in the corridor, state agencies, regional planning commissions, and several non-profit organizations. The purpose of CTAP is to promote beneficial growth patterns and development practices that minimize the negative effects of growth on community services, remaining open space, schools, traffic patterns, environmental quality, and existing residential and commercial development. The CTAP initiative consists of several projects, one of which is a buildout analysis. A standardized buildout analysis will be completed for each of the 26 CTAP communities.

### What is a Buildout?

A buildout is a tool that allows planners to estimate future development based on different scenarios. This buildout is an analysis of existing adopted municipal policy. The buildout method allows for the potential testing of alternative land use regulation, open space planning and major development scenarios. A buildout consists of one

**The Buildout analysis shows the maximum growth that is likely to occur in a community under current land use regulations (zoning).**

or more scenarios. This buildout contains three scenarios: base, standard alternative, and community alternative. The process is designed with the capability for conducting future alternative scenario testing.

Comparing various scenarios allows planners to test the effects and consequences of new zoning ordinances. Changing setbacks, densities, and building restrictions can significantly alter a buildout. The analysis of results allows planners to evaluate the effectiveness and viability of changes to the zoning code. Questions that can be answered by a buildout scenario testing include: Where do I want my community to be at buildout? How much open space will there be? What will the traffic patterns look like? What will the quality of our environmental resources be like? Where will people live and what will the development patterns look like? The purpose of CTAP is to promote beneficial answers to all of these

questions. The CTAP program aims to achieve goals that cover four themes: community infrastructure, environment protection, land use, and open space, downtown/village centers and community vitality and the local economy. The CTAP Buildout project is a community empowerment tool to help people make the best long-term planning decisions.

### What a Buildout is not?

A Buildout is not a prediction of what will occur. It is a planning tool to allow community decision makers to understand the impacts of growth under a set of land use rules. In addition, the Community Specified scenarios in this report do not necessarily represent official policy goals or a plan for the community, but are merely a test of one alternative growth scenario.

### Scenario Planning

Scenarios are an analysis about what might be. They are not predictions about what will happen but they are possible futures based on what already exists, on current trends, and on the values and on the preferences of a community. Each community is unique and may have different goals and face

different challenges to how it will change over time. The scenarios in this report are based on both standardized methods, repeated for each CTAP Community, and a scenario where the details have been specified by community leaders and stakeholders. The scenarios are built as a way to compare outcomes and learn about the potential effects of government policies over a long span of time. Because the analysis is quantitative, scenarios can be compared directly utilizing charts and maps. The point is to help discover which long-term growth scenarios our preferable and most closely match the goals and values of the community.

### Report Template

The format of this report is a template that will be used to uniformly present the buildout results for each of the 26 communities in the CTAP Region. Maps, charts and a few paragraphs of text will change for each community. This report presents only the results of the buildout scenarios. It does not attempt to be a planning analysis of those results. Each Community Report will contain the same Introduction and Overview sections on the process. Only maps, charts and the Community Scenario section will change for each different community.

### **Buildout questions:**

- **Where do I want my community to be at buildout?**
- **How much open space will there be?**
- **What will the traffic patterns look like?**
- **What will the quality of our environmental resources be like?**
- **Where will people live and what will the development patterns look like?**

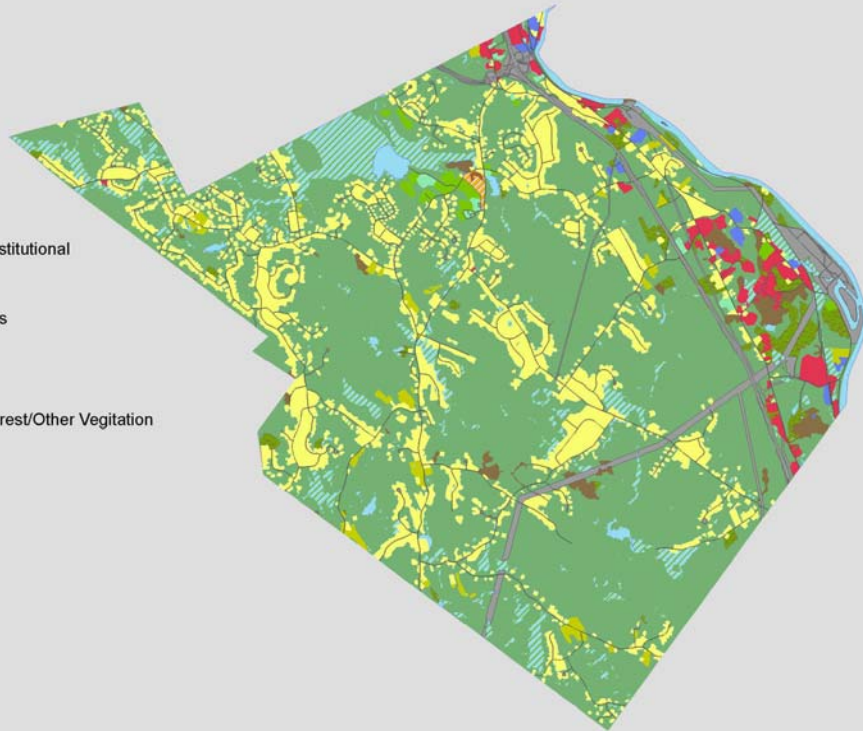

## Methods

### Tools and Data

Buildouts were conducted using Geographic Information systems (GIS) software. The application used for this project is developed by the mapping software company ESRI. ArcMap and CommunityViz are the core programs used in the analysis. The CommunityViz program is an extension that works with ArcMap and is used specifically to perform buildout analyses. CommunityViz was developed by the Orton Family Foundation in order to provide communities with an affordable tool to perform buildout studies.

The GIS data used in this study originates from several sources. The base shapefiles (road centerlines, conservation lands, wetlands, etc.) were provided by GRANIT, the official New Hampshire GIS data provider. The land use polygons were created through a prior CTAP project, using 2005 aerial images provided by the NH Department of Transportation. The classification applied to the land use polygons is very detailed, using over 50 land uses. The current building points were also determined using the 2005 aerial images.

## CTAP Existing Land Use

# Bow Zoning

## Zoning

- Residential
- Rural
- Commercial
- Limited Industrial
- Business Development District
- Institutional
- Civic District
- General Industrial

## Procedures

To complete the buildouts a CTAP Buildout Working Group was established. Members of the group consisted of the Four Regional Planning Commissions, who would be performing the analysis: Central New Hampshire Regional Planning Commission, Nashua Regional Planning Commission, Rockingham Regional Planning Commission & Southern New Hampshire Regional Planning Commission. This group was responsible for defining the tools, methods and procedures for performing the buildouts. The group is also responsible for the format of the presentation of results. Staff from each Regional Planning Commission conducted the buildout for communities in their region.

All CTAP buildouts follow the same basic procedures allowing them to be combined upon completion. The existing data used for each municipality is obtained from statewide layers, and clipped for each town. The data created for the buildout follows a strict set of guidelines in order to produce a uniform set for the CTAP region.

CommunityViz software uses the land use and zoning inputs with the constraint layers to create a buildable area GIS layer. First a numeric buildout is calculated using lot size and allowable density information. Next a spatial buildout is conducted. This process takes into account spatial restrictions (i.e. Setbacks from roads, distance between buildings). The spatial restrictions for the base buildout are determined using the current zoning ordinances. This produces a layer of new estimated buildings and places them as points

## Map layers used in the Buildout Analysis.

### Land use inputs:

- CTAP Land Use - based on 2005 Aerial Imagery
- Zoning
- Current Building points - based on 2005 Aerial Imagery
- Community Centers - NHDES Sprawl Indicators data, NH GRANIT
- Road Centerlines - NHDOT, NH GRANIT
- Transit Stops - Derived from local data
- Sewer Service Areas - NHDES, NH GRANIT

### Constraint layers:

- Wetlands, National Wetland Inventory (NWI) - NH GRANIT
- 100-Year Floodplain - FEMA, NH GRANIT
- Conservation Lands - Local data & NH GRANIT
- Natural Services Network (NSN) - Jordan Institute, NH GRANIT

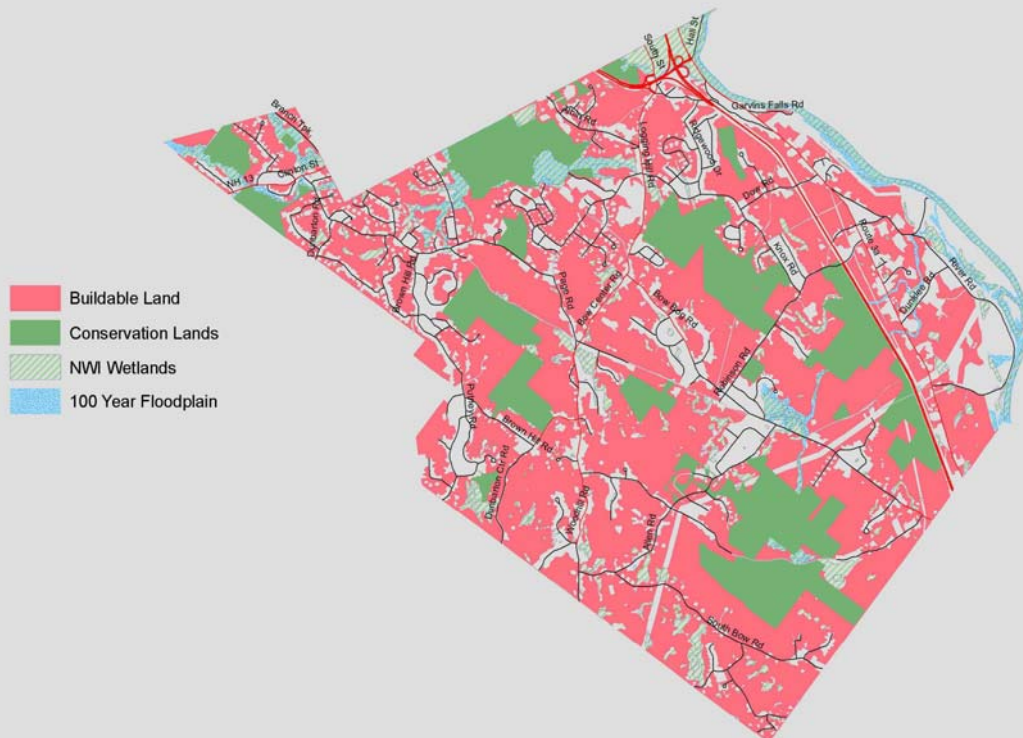

on the map. Standard Alternative and Community Alternative Buildouts use the same process with adjustments to the land use rules (Zoning changes, allowable uses & allowable densities) that are specified in those scenarios.

Once the buildout is complete, a template, containing all assumptions, indicators and charts is applied. All indicators are calculated from the basic buildout results. The standard template ensures that the calculations and charts are the same for all of the region's buildouts.

Detailed input and output reports, produced directly from the CommunityViz software, are available in Appendix A.

## Developable Lands & Constraints

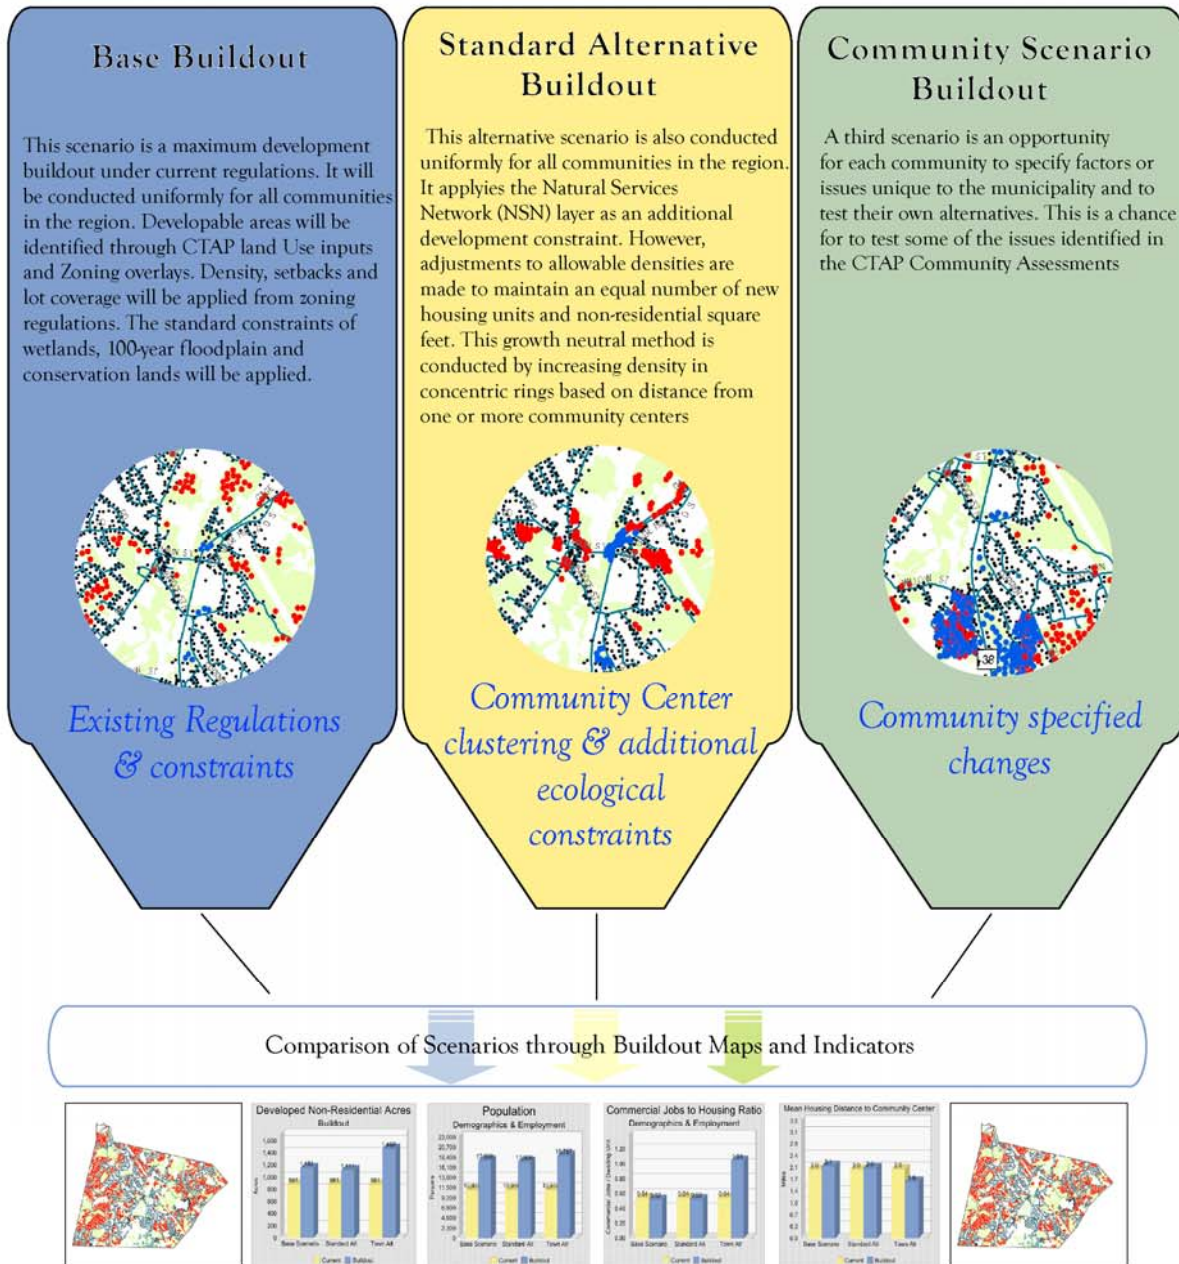

## Buildout Scenarios

This report tests and compares three alternative scenarios for growth. Each scenario produces different land use patterns, different densities and different development totals. The mix of jobs and housing, available open space, traffic, schools, water and air quality and community character are all impacted in different ways. By comparing the maps and charts produced by each scenario, a community can analyze how that growth pattern will affect their city of town.

## Base Scenario

The first scenario, conducted for all communities, is the Base Scenario. This scenario represents what buildout would look like following the current land use regulations. Density, setbacks and lot coverage is applied from the current zoning regulations. The standard development constraints of wetlands, 100-year floodplain and conservation lands are applied.

If current zoning is a blueprint for how the community should grow then this scenario is the culmination of the existing regulations. The indicators in this report are meant to portray a wide range of conditions at buildout. Development

growth means more than additional persons, houses or commercial buildings. It can have impacts on

If current zoning is a blueprint for how the community should grow then the Base Buildout Scenario is the culmination of the existing regulations.

finances, traffic, municipal services, environmental quality and sense of community or place. The land use pattern for how a community grows, where development will take place and in what densities, can also have a significant impact.

## Base Buildout

- Current Buildings
- Base Buildout Buildings**
  - Single Family Residential
  - Non-Residential
- Buildable Land

### Standard Alternative

The standard alternative scenario will also be conducted uniformly for all communities in the region. The scenario is different from the Base Scenario in a couple of key ways. First, it applies the Natural Services Network (NSN) layer as an additional development constraint. Second, adjustments to allowable densities will be made to maintain an equal number of new housing units and non-residential square feet. This growth neutral method will be conducted by increasing density in concentric rings based on distance from one or more community centers.

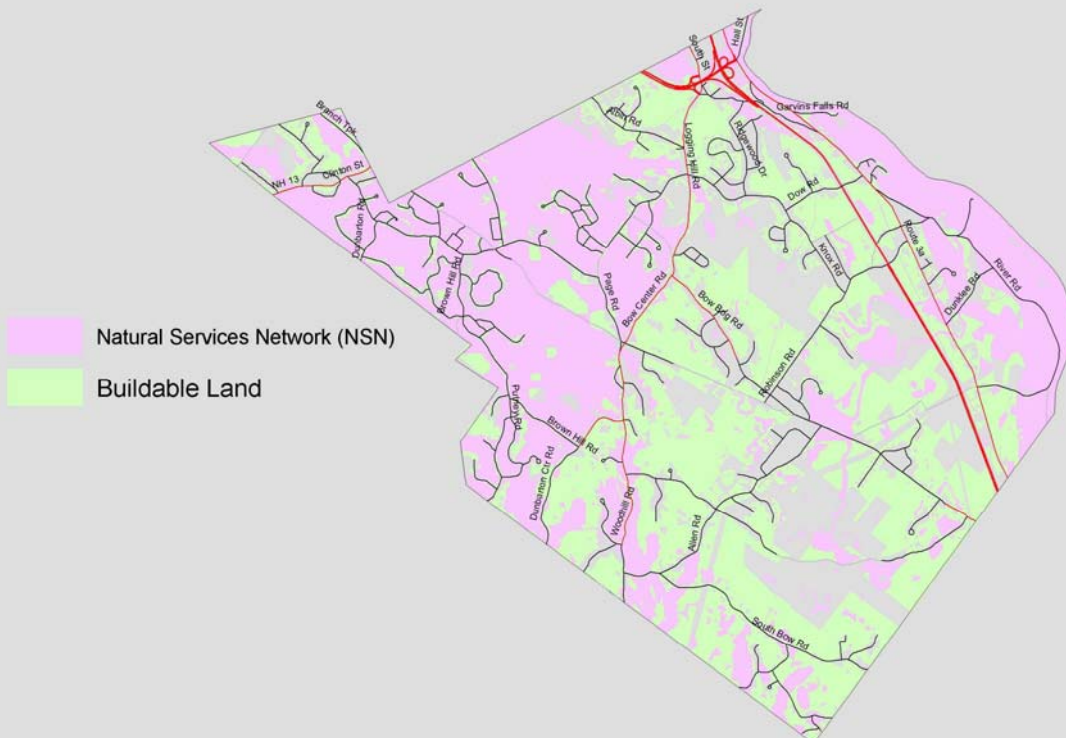

This scenario is focused on creating densely developed downtown areas, sparing important ecological areas identified in the Natural Services

network (NSN). The NSN is a co-occurrence analysis and includes four components: water supply lands, flood storage lands, productive soils, and important wildlife habitat.

The Standard Alternative Scenario does not represent a policy proposal for the community. It is a standardized method to analyze an alternative growth scenario that can be applied uniformly to all CTAP communities.

## Natural Services Network Constraint

The key to the Standard Alternative Scenario is to adjust allowable development densities so that an approximately equal amount of growth occurs as the Base Buildout despite the fact that more land has been set aside as un-buildable. This scenario is applying a standardized, uniform growth alternative to all communities in the CTAP region. It is not

limiting the amount of commercial and residential growth that might occur in the community, but it is managing it differently.

#### Standard Alternative Scenario:

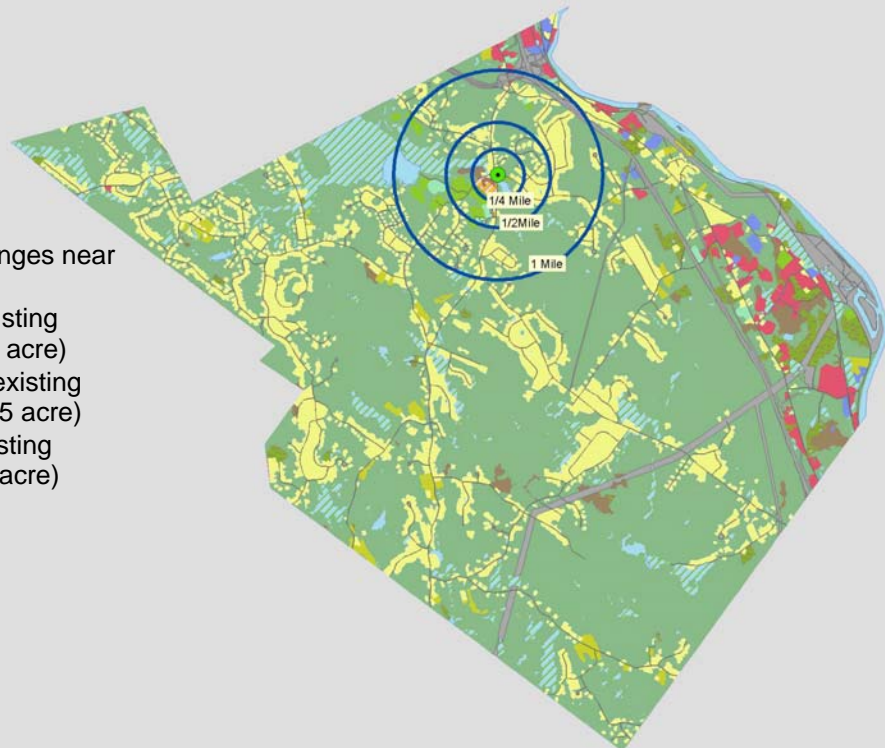

- NSN added as additional development constraint.
- Greater density around community centers.
- Same amount of growth as base scenario

## Standard Alternative Density Changes

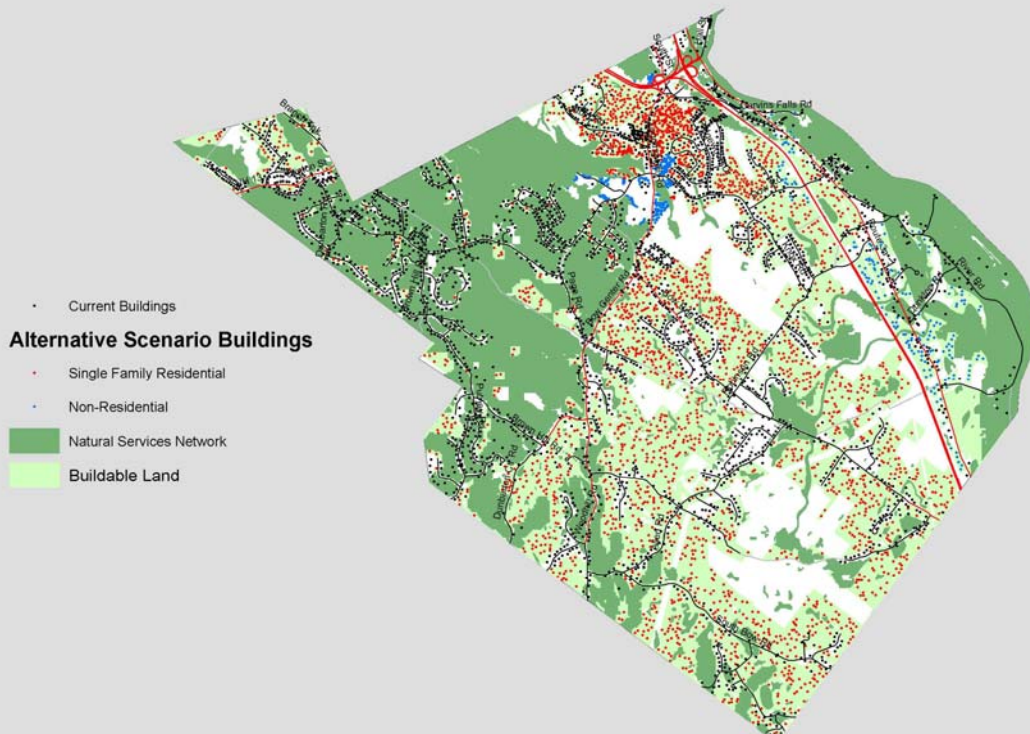

#### Residential Density changes near Community Center

- ¼ Mile – 4 times existing zoning density (.5 acre)
- ½ Mile - 2.7 times existing zoning density (.75 acre)
- 1 Mile - 2 times existing zoning density (1 acre)

## Standard Alternative Buildout

### Method Adjustments Made in Base and Standard Alternative Buildouts

Based on input from the Town of Bow Planning Board, two adjustments were made to the buildout methods to produce more accurate results:

- Development efficiencies were decreased from 85% to 65% on all residential areas due to recent history, land categorized as “buildable” on portions of undividable lots, steep slopes, and access issues on a variety of parcels in town.
- The land use “Strip Mine/Quarry or Gravel Pit” was considered “buildable” as these areas are located in places deemed suitable for development.

### Community Alternative

A third scenario was provided for each community to specify factors or issues unique to the municipality and to test their own alternatives. This scenario is known as the **community alternative**. This is a

The Community Alternative scenario is only a test of an alternative growth pattern. It is a planning tool conducted to see what changes might occur. It does not necessarily represent a policy plan for the community

chance for certain properties to be removed or added to the developable areas list or for particular regulation changes to be implemented. In order to

get the community's input for their scenario, meetings were conducted with local officials and volunteers. This was an opportunity for the community leaders to test what would occur if their Town or City were to grow in a different way. This is a chance to apply goals specified in Master Plan or other planning document, or to test the affects of purchasing large tracts of land for conservation.

The Community Alternative scenario is only a test of an alternative growth pattern. It is a planning tool conducted to see what changes might occur. It does not necessarily represent a policy plan for the community. Unlike the Standard Alternative Scenario, the Community Scenario does not require growth to be the equal to the Base Buildout. Significantly lower or greater amounts of development are possible.

## Town Alternative Scenario

New  
Mixed Use  
Nodes

Conservation  
Subdivision  
Areas

The Pelham Community Scenario consists of new mixed use, higher density nodes and a new conservation subdivision regulation applied to two large residential areas. Pelham is working on an Economic Development Plan through CTAP Discretionary funding and in conjunction with that plan the community buildout was used to test potential development patterns for new commercial and multi-family residential growth. New mixed use overlays were applied in six locations: the existing town center, adjacent to the industrial park on Route 128, off of Route 128 on the south border with Dracut, on Route 38 south of Willow Street - extending the Business Zoning District east & west, on Route 38 north of the town center - extending the Business District north and on Route 38 near the Windham border.

Changes in these mixed use areas include higher densities for commercial and residential development and mixed use structures. Several of the new overlays assume some redevelopment of existing housing.

Two new conservation subdivision overlays were established, one in the northwest corner of town and one in the Little Island Pond area. These overlays required 50% of the land to be set aside as conservation and allowed double the density on the remaining 50%.

## Indicators

Indicators are impact or performance measures that help people choose alternatives that best match their objectives or desired outcomes. An indicator is a calculated value that represents the impacts or outcomes of a scenario. An indicator might be used to evaluate costs, revenues, average household size, or total daily auto trips. The buildout indicators in this report are meant to provide a macro, overall picture of how a community could look at buildout.

Comparing indicators by the different buildout scenarios provides an assessment of the effects different development patterns may have. There are 40 indicators arranged in seven categories: Buildout, Demographics & Employment, Environmental & Open Space, Land Use Characteristics, Municipal Demands, Water & Energy Use & Transportation. The following pages explain what each indicator means and chart the differences by scenario.

Category	Indicator	Units	Current	Base Buildout	Percent Change	Standard Alternative Scenario	Percent Change	Town Scenario	Percent Change
Buildout	Developed Residential Acres	Acres	5,084	11,082	118%	10,548	107%	10,211	101%

Indicators - MUNICIPAL DEMANDS cont.

 INDICATORS	Indicator: <b>SOLID WASTE DEMAND</b>			
MUNICIPAL DEMANDS				
Description: <i>Total amount of solid waste produced</i>  The solid waste demand represents the total amount of solid waste produced by the town’s population in a year. In 2005 the EPA stated that the average person in the US produces 54 tons of solid waste per year. This number is combined with the total population to determine the yearly solid waste demand for the municipality				
Source: <i>US average from the EPA, 2005</i>

## Indicators - WATER AND ENERGY USE cont.

 INDICATORS	Indicator: <b>COMMERCIAL ENERGY USE</b>			
	WATER AND ENERGY USE			
<p>Description: <i>Total annual energy used by non-residential buildings for all applications, including electricity and heating.</i></p> <p>This indicator was calculated using the square footage of commercial buildings. The average commercial building uses 99.8 thousand btu/sq ft. The new buildings created by the software have a standard size based upon the median square feet of the existing commercial and industrial buildings. The square footages for the commercial buildings created by the buildout are based on the median of the existing commercial and industrial building sizes in the municipality.</p> <p>Source: <i>Energy Information Administration, 2003 Northeast Commercial Buildings Energy Consumption Survey of 2003</i></p>				
Value: mbtu/hh/yr <b>CURRENT</b>	<b>BASE BUILDOUT</b>	<b>STANDARD ALTERNATIVE</b>	<b>COMMUNITY SCENARIO</b>

 INDICATORS	Indicator: <b>RESIDENTIAL WATER USE</b>			
	WATER AND ENERGY USE			
<p>Description: <i>Total annual water used by residential buildings</i></p> <p>Residential water use is the total amount of water used by residential buildings. According to the US Geological Survey the average dwelling unit uses 391 gallons of water per day. This number was then multiplied by 365 and the number of dwelling units resulting in the annual residential water consumption. This indicator is especially significant for urbanized areas that offer municipal water service.</p> <p>Source: <i>US Geological Survey,</i></p>

## Indicators - TRANSPORTATION cont.

 INDICATORS	Indicator: ANNUAL CO AUTO EMISSIONS			
TRANSPORTATION				
<p>Description: <i>Total carbon monoxide emissions generated by vehicles associated with residential buildings</i></p> <p>The annual CO auto emissions is the yearly total of carbon monoxide emissions generated by vehicles associated with residential buildings. The average trip length of 9.78 miles is divided by the average car efficiency of 24 mpg to determine the number of gallons of gas per trip. This number is then multiplied by the average number of trips per day. The number of trips is 5.86 for multi-family residences and 9.57 for single family residences. This number is then multiplied by the pounds of CO released from the burning of a gallon of gas. This indicator is important because it shows that different land uses can greatly reduce the amount of greenhouse gases released.</p>
